ABSTRACT

We develop in this paper a new procedure to construct simultaneous confidence bands for derivatives of mean curves in functional data analysis. The technique involves polynomial splines that provide an approximation to the derivatives of the mean functions, the covariance functions and the associated eigenfunctions. We show that the proposed procedure has desirable statistical properties. In particular, we first show that the proposed estimators of derivatives of the mean curves are semiparametrically efficient. Second, we establish consistency results for derivatives of covariance functions and their eigenfunctions. Most importantly, we show that the proposed spline confidence bands are asymptotically efficient as if all random trajectories were observed with no error. Finally, the confidence band procedure is illustrated through numerical simulation studies and a real life example.

1. Introduction

Functional data analysis (FDA) is a relatively new field in statistics, where the data are typically curves or high-dimensional surfaces. In exploratory FDA, it is often of interest to estimate the mean functions; see for example, Ramsay and Silverman (2005), Yao et al. (2005a,b), Ferraty and Vieu (1996), Li and Hsing (2010) and Cao et al. (forthcoming). In some settings, however, estimation and inference of derivatives of the mean functions in FDA are of equal importance. For example, in economics, consistent and direct estimation of derivatives are essential for estimating elasticities, returns to scale, substitution rates and average derivatives. Often, these index (derivative) functions are as interesting as the mean functions themselves. Another example is in the fields of engineering and biomedical sciences, where the estimation of velocity and acceleration are of great importance in addition to obtaining a smooth curve of the measurements.

The problem of estimation and inference of derivatives for functional data is very challenging; see Ramsay and Silverman (2005), Liu and Müller (2009), and Hall et al. (2009) for some discussions. Existing methodologies for derivatives of the regression function in FDA often rely on a pointwise analysis. For example, in Liu and Müller (2009) the theoretical focus was primarily on obtaining consistency and asymptotic normality of the proposed estimators, thereby providing the necessary ingredients to construct pointwise confidence intervals. This approach is important but its usefulness in conducting global inferences is limited. To our knowledge, we are not aware of any methodology that provides simultaneous confidence bands for functional derivatives in FDA. In this paper, we develop such methodology with the primary aim to better understand the variability and shape of the mean curve.
Nonparametric simultaneous confidence bands are powerful tools for global inference of functions. Some work has been conducted to study the simultaneous confidence band of the mean curves for FDA; see Degras (2011), Ma et al. (2012) and Cao et al. (forthcoming). The research work on confidence bands for functional derivatives is actually sparse. This is partially due to the technical difficulty to formulate such bands for FDA and establish the associated theoretical properties.

Some smoothing tools are necessary to construct the confidence bands. Popular smoothing methods include kernels (Gasser and Müller, 1984; Härde, 1989; Xia, 1998; Claeskens and Van Keilegom, 2003), local polynomials (Fan and Gijbels, 1996), splines (Wahba, 1990; Stone, 1994) and series expansion methods (Morris and Carroll, 2006). In this paper, we use B-splines, which can be readily implemented due to their explicit expression, to construct the bands. B-spline approximation has also been employed to estimate the functional mixed-effect models in Shi et al. (1996) and Rice and Wu (2001), and to study functional data via principle components in Yao and Lee (2006) and Zhou et al. (2008). Other works include Zhou et al. (1998) and Wang and Yang (2009a) who have proposed B-spline confidence bands for regression functions.

The proposed confidence bands are asymptotically the same as if all the random trajectories are correctly recorded over the entire interval. As discussed in Section 2.3, the estimators are semiparametrically efficient thereby providing partial theoretical justification for treating functional data as perfectly recorded random curves over the entire data range, as in Cao et al. (forthcoming).

The rest of the paper is organized as follows. In Section 2, we introduce the model and the spline estimators for the mean curves and their derivatives. Section 3 presents the simultaneous confidence bands for the derivatives of the mean curves. Specifically, in Section 3.1, we show that the bands have asymptotically correct coverage probabilities; and in Section 3.2, we discuss how to estimate the unknown components involved in the band construction and other issues of the implementation. Section 4 reports findings from a simulation study and a real data set. Proofs of technical results are relegated to Appendix.

2. Models and spline estimators

2.1. Models

We consider a collection of trajectories \( \{X_i(t)\}_{i=1}^n \) which are i.i.d. realizations of a smooth random function \( X(t) \), defined on a continuous interval \( T \). Assume that \( X(t), t \in T \) is a \( \mathcal{L}^2(T) \) process, i.e. \( E \int_T X^2(t) \, dt < +\infty \), and define the mean and covariance functions as \( \mu(t) = E[X(t)] \) and \( \Gamma(t,s) = \text{cov}(X(t),X(s)), \) \( t,s \in T \). The covariance function is a symmetric nonnegative-definite function with a spectral decomposition, \( \Gamma(t,s) = \sum_{k=1}^{\infty} \lambda_k \phi_k(t) \phi_k(s) \), where \( \lambda_1 \geq \lambda_2 \geq \cdots \geq 0 \), are the eigenvalues satisfying \( \sum_{k=1}^{\infty} \lambda_k < \infty \), and \( \{\phi_k(t)\}_{k=1}^{\infty} \) are the corresponding eigenfunctions that form an orthonormal basis. By the standard Karhunen–Loève representation (Hall and Hosseini-Nasab, 2006), \( X_i(t) = \mu(t) + \sum_{k=1}^{\infty} \xi_{ik} \phi_k(t) \), where the random coefficients \( \xi_{ik} \) are uncorrelated with mean 0 and variance \( \lambda_k \). In what follows, we assume that \( \lambda_k = 0 \), for \( k > \kappa \), where \( \kappa \) is a positive integer or \( \infty \).

We consider a typical functional data setting where \( X_i(\cdot) \) is recorded on a regular grid in \( T \), and assumed to be contaminated with measurement errors. Without loss of generality, we take \( T = [0, 1] \). Then the observed data are \( Y_{ij} = X_i(T_j) + \epsilon_{ij}, \) for \( 1 \leq i \leq n, 1 \leq j \leq N \), where \( T_j = j/N, \) \( \epsilon_{ij} \) are independent random errors with \( E(\epsilon_{ij}) = 0 \) and \( E(\epsilon_{ij}^2) = 1 \), and \( \sigma(\cdot) \) is the standard deviation of the measurement errors. By the Karhunen–Loève representation, the observed data can be written as

\[
Y_{ij} = \mu(j/N) + \sum_{k=1}^{\kappa} \xi_{ik} \phi_k(j/N) + \sigma(j/N) \epsilon_{ij},
\]

where \( \mu(\cdot), \sigma(\cdot) \) and \( \{\phi_k(\cdot)\}_{k=1}^{\kappa} \) are smooth but unknown functions of \( t \). In addition, \( \{\phi_k(\cdot)\}_{k=1}^{\kappa} \) are further subject to constraints \( \int_0^1 \phi_k^2(t) \, dt = 1 \), and \( \int_0^1 \phi_k(t) \phi_{k'}(t) \, dt = 0 \), for \( k \neq k' \).

2.2. Spline estimators

We first introduce some notation of the B-spline space. Divide the interval \( T = [0, 1] \) into \( (N+1) \) subintervals \( I_j = [\omega_j, \omega_{j+1}), \) \( j = 0, \ldots, N \) \( -1 \) intervals \( I_j = [0, N \) \( +1, 1 \) \( \} \) \( \omega_{N+1} = 1 \), where \( \omega_{p+1} := \{\omega_j\}_{j=1}^{N+1} \) is a sequence of equally spaced points, called interior knots. Let \( \mathcal{P}^{(p-2)} \) be the polynomial spline space of order \( p \) on \( [0,1] \). This space consists of all \( p-2 \) times continuously differentiable functions on \([0,1]\) that are polynomials of degree \( p-1 \) on each interval \( I_j \). The \( j \)-th B-spline of order \( p \) is denoted by \( B_{j,p} \). We augment the boundary and the number of interior knots as \( \omega_{0} = \cdots = \omega_{p} = 0 < \omega_{1} < \cdots < \omega_{N+1} = 1 = \omega_{N+1} = \cdots = \omega_{N+p} \), in which \( \omega_{j} = h_{j,p}, \) \( j = 0, 1, \ldots, N+1 \) and \( \omega_{j} = 1/(N+1) \) is the distance between neighboring knots.

Following Cao et al. (forthcoming), we estimate the mean function \( \mu(\cdot) \) in (1) by

\[
\hat{\mu}(\cdot) = \arg \min_{g(\cdot) \in \mathcal{P}^{(p-2)}} \sum_{i=1}^{n} \sum_{j=1}^{N} \{Y_{ij} - g(j/N)\}^2 = \sum_{j=1}^{N} \hat{b}_{j,p} B_{j,p}(\cdot),
\]
where the coefficients
\[
\hat{b}_p = (\hat{b}_{1-p}, \ldots, \hat{b}_{N_p})^T = \arg\min_{\mathbb{R}^{N_p}} \sum_{i=1}^{n} \sum_{j=1}^{N} \left\{ Y_{ij} - \sum_{j'=1}^{N_p} \beta_{j'} Y_{i,j'} \right\}^2.
\]

Let \( Y \equiv (Y_1, \ldots, Y_N)^T \) and \( Y_j \equiv n^{-1} \sum_{i=1}^{n} Y_{ij}, 1 \leq j \leq N \). Applying elementary algebra, one obtains
\[
\hat{\mu}(t) = B_p(t) \hat{b} B Y,
\]
in which \( B_p(t) = (B_{1-p}(t), \ldots, B_{N_p}(t)) \) and \( B = (B_p(1/N), \ldots, B_p(N/N))^T \) is the design matrix.

We denote by \( \hat{\mu}^{(v)}(t) \) the \( v \)-th order derivative of \( \hat{\mu}(t) \) with respect to \( t \). Since \( \hat{\mu}(t) \) is an estimator of \( \mu(t) \), it is natural to consider \( \hat{\mu}^{(v)}(t) \) as the estimator of \( \mu^{(v)}(t) \), for any \( v = 1, \ldots, p-2 \), i.e.
\[
\hat{\mu}^{(v)}(t) = B_p^{(v)}(t) \hat{b} B Y,
\]
where \( B_p^{(v)}(t) = (B_{1-p}^{(v)}(t), \ldots, B_{N_p}^{(v)}(t)) \). According to B-spline property in de Boor (2001), for \( p > 2 \) and \( 2-p \leq j \leq N_p-1 \),
\[
\frac{d}{dt} B_{j,p}(t) = (p-1) \frac{B_{j-1,p-1}(t) - B_{j+1,p-1}(t)}{\beta_{j} - \beta_{j+1}}.
\]
Therefore, \( B_p^{(v)}(t) = B_{p,v}(t) D(t) \) in which \( D(t) = D_1 \cdots D_{v-1} D_v \), with matrix
\[
D_l = (p-l) \begin{pmatrix}
\frac{1}{\beta_{l+1}-\beta_l} & 0 & \cdots & 0 \\
\frac{1}{\beta_{l+2}-\beta_{l+1}} & \frac{1}{\beta_{l+3}-\beta_{l+2}} & \cdots & 0 \\
\vdots & \vdots & \ddots & \vdots \\
0 & 0 & \cdots & \frac{1}{\beta_{N_p-l}}
\end{pmatrix}
\]
for \( 1 \leq l \leq v \leq p-2 \), which is the same as Eq. (6) in Zhou and Wolfe (2000).

2.3. Asymptotic convergence rate

Define the following “infeasible estimator” of function \( \mu^{(v)} \)
\[
\pi_i^{(v)}(t) = X_i^{(v)}(t) = n^{-1} \sum_{i=1}^{n} X_i^{(v)}(t), \quad t \in [0,1].
\]
The term “infeasible”, borrowed from Cao et al. (forthcoming), refers to the fact that \( \pi^{(v)}(t) \) would be a natural estimator of \( \mu^{(v)}(t) \) if all random curves \( X_i^{(v)}(t) \) were observed. In the following, we want to show that the spline estimator \( \hat{\mu}^{(v)}(t) \) in (3) is asymptotically equivalent to \( \pi^{(v)}(t) \).

We break the error \( \hat{\mu}^{(v)}(t) - \mu^{(v)}(t) \) into three terms. Let \( \tau_i = n^{-1} \sum_{j=1}^{n} \xi_{ij}, 1 \leq j \leq N \). Denote the signal vector, the noise vector and the eigenfunction vectors by \( \mu = (\mu(1/N), \ldots, \mu(N/N))^T \), \( e = (\sigma(1/N) \xi, \ldots, \sigma(N/N) \xi)^T \) and \( \phi = (\phi(1/N), \ldots, \phi(N/N))^T \). Projecting the relationship in model (2) onto the linear subspace of \( \mathbb{R}^{N_p+p} \) spanned by \( \{B_p(\hat{\nu}), \hat{\nu} \} \), \( 1 \leq \hat{\nu} \leq N_p \leq N \), we obtain the following crucial decomposition:
\[
\hat{\mu}^{(v)}(t) = \hat{\mu}^{(v)}(t) + \hat{\varepsilon}^{(v)}(t) + \hat{\zeta}^{(v)}(t),
\]
where \( \hat{\mu}^{(v)}(t) = I^{(v)}(t) \mu, \hat{\varepsilon}^{(v)}(t) = I^{(v)}(t) e \) and \( \hat{\zeta}^{(v)}(t) = \sum_{k=1}^{K} \xi_{kk} I^{(v)}(t) \phi_k \) with \( I^{(v)}(t) = B_p^{(v)}(t) B Y^{-1} B Y \) and \( \xi_{kk} = n^{-1} \sum_{i=1}^{n} \xi_{ik}, 1 \leq k \leq K \).

The following proposition provides asymptotic properties of the three terms.

Proposition 1. Under Assumptions (A1)–(A6) in Appendix, one has
\[
\sup_{t \in [0,1]} |\hat{\mu}^{(v)}(t) - \mu^{(v)}(t)| = o(n^{-1/2}),
\]
\[
\sup_{t \in [0,1]} |\hat{\zeta}^{(v)}(t) - (\pi^{(v)}(t) - \mu^{(v)}(t))| = o_p(n^{-1/2}),
\]
\[
\sup_{t \in [0,1]} |\hat{\varepsilon}^{(v)}(t)| = o_p(n^{-1/2}).
\]

Appendix A.2 contains proofs for the above proposition, which together with (5), leads to the following semiparametric efficiency result.
Theorem 1. Under Assumptions (A1)–(A6) in Appendix, the B-spline estimator \( \hat{\mu}^{(v)} \) is asymptotically equivalent to \( \overline{\mu}^{(v)} \) with the \( \sqrt{n} \) approximation power, i.e.
\[
\sup_{t \in [0, 1]} |\hat{\mu}^{(v)}(t) - \overline{\mu}^{(v)}(t)| = O_P(n^{-1/2}).
\]

Remark 1. Since the “infeasible estimator” \( \overline{\mu}^{(v)}(t) \) is the sample average of i.i.d. trajectories \( \{X_i(t)\}_{i=1}^n \), an application of the central limit theorem gives \( \sup_{t \in [0, 1]} |\hat{\mu}^{(v)}(t) - \mu^{(v)}(t)| = O_P(n^{-1/2}) \). Thus combining with the results in Theorem 1, one has
\[
\sup_{t \in [0, 1]} |\hat{\mu}^{(v)}(t) - \mu^{(v)}(t)| = O_P(n^{-1/2}).
\]

3. Confidence bands

In this section, we develop the simultaneous confidence bands for the derivative function \( \mu^{(v)}(t) \).

3.1. Asymptotic confidence bands

Let \( \Sigma(\cdot, \cdot) \) be a positive definite function, and defined as \( \Sigma(t,s) = \sum_{k=1}^{K} \gamma_{k} \phi'_k(t) \phi'_k(s), t, s \in [0, 1] \). Denote by \( \zeta(t), t \in [0, 1] \) a standardized Gaussian process such that \( E \zeta(t) = 0, \ E \zeta^2(t) = 1 \) with covariance function \( E \zeta(t) \zeta(s) = \Sigma(t,s) \Sigma(s,s)^{-1/2}, t, s \in [0, 1] \). Denote by \( q_{1-\alpha} \) the 100\((1-\alpha)\)th percentile of the absolute maxima distribution of \( \zeta(t), t \in [0, 1] \), i.e.
\[
P(\sup_{t \in [0, 1]} |\zeta(t)| \leq q_{1-\alpha}) = 1 - \alpha, \ \forall \alpha \in (0, 1).
\]

Theorem 2. Under Assumptions (A1)–(A6) in Appendix, \( \forall \alpha \in (0, 1) \), as \( n \to \infty \),
\[
P \left\{ \sup_{t \in [0, 1]} n^{1/2} |\overline{\mu}^{(v)}(t) - \mu^{(v)}(t)| \Sigma(t,t)^{-1/2} \leq q_{1-\alpha} \right\} \to 1 - \alpha.
\]

Applying Theorems 1 and 2 gives asymptotic confidence bands for \( \mu^{(v)}(t), t \in [0, 1] \).

Corollary 1. Under Assumptions (A1)–(A6) in Appendix, \( \forall \alpha \in (0, 1) \), as \( n \to \infty \), an asymptotic 100 \((1-\alpha)\)% exact confidence band for \( \mu^{(v)}(t) \) is
\[
P(\mu^{(v)}(t) \in \hat{\mu}^{(v)}(t) \pm n^{-1/2} q_{1-\alpha} \Sigma(t,t)^{1/2}, \ t \in [0, 1]) \to 1 - \alpha.
\]

3.2. Implementation

When constructing the confidence bands, one needs to estimate the unknown function \( \Sigma(t,s) \). Note that \( \Sigma(t,s) = G(t,s) \), when \( v = 0 \). Following Liu and Müller (2009), we estimate \( \phi'_k(t) \) through the derivatives of \( G(t,s) \). According to Cao et al. (2011), \( G(t,s) \) is estimated by
\[
\hat{G}(t,s) = \sum_{j=1}^{H} \hat{b}_{jj} B_{jj}(t) B_{jj}(s),
\]
where \( \hat{R}_{jj} = n^{-1} \sum_{i=1}^{n} (Y_i - \hat{\mu}(j/N)) (Y_i - \hat{\mu}(j/N)) \), \( 1 \leq j 
eq k \leq N, \ N_c \) is the number of interior knots for B-spline, and the coefficients
\[
\{\hat{b}_{jj}\}_{jj=1-p} = \arg \min_{(\hat{b}_{jj})_{jj=1-p}} \sum_{j=1}^{N} \left\{ \hat{R}_{jj} - \sum_{1-p \leq j' \leq N_c} b_{jj} B_{jj}(j/N) B_{jj}(j'/N) \right\}^2
\]
with “\( \otimes \)” being the tensor product of two spaces. They showed that \( \hat{G} \) converges to \( G \) as \( n \) goes to \( \infty \). In this section, we further show that \( \hat{G} \) and \( G \) are asymptotically equivalent up to the \( v \)-th partial derivative. We define the \( v \)-th derivative with respect to \( s \) for \( G(t,s) \) and \( \hat{G}(t,s) \) as
\[
G^{(v)}(t,s) = \frac{\partial^v}{\partial^v s} G(t,s), \quad \hat{G}^{(v)}(t,s) = \frac{\partial^v}{\partial^v s} \hat{G}(t,s) = \sum_{jj} \hat{b}_{jj} B_{jj}(t) B'_{jj}(s).
\]

Theorem 3. Under Assumptions (A1)–(A6), one has
\[
\sup_{(t,s) \in [0, 1]^2} |\hat{G}^{(v)}(t,s) - G^{(v)}(t,s)| = O_P(1), \quad 1 \leq v \leq p-2.
\]

The proof of Theorem 3 is given in Appendix A.3.
According to Liu and Müller (2009), we estimate the $v$-th derivative of eigenfunctions $\hat{\phi}^{(v)}_k$ using the following eigenequations:

$$
\frac{d^v}{ds^v} \int_0^1 \hat{G}(t,s)\hat{\phi}_k(t)\,dt = \int_0^1 \frac{d^v}{ds^v} \hat{G}(t,s)\hat{\phi}_k(t)\,dt = \hat{\lambda}_k \hat{\phi}^{(v)}_k(s),
$$

(11)

where $\hat{\phi}_k$ are subject to $\int_0^1 \hat{\phi}_k(t)\,dt = 1$ and $\int_0^1 \hat{\phi}_k(t)\hat{\phi}_k(t)\,dt = 0$ for $k < k$. If $N$ is sufficiently large, the left hand side of (11) can be approximated by $(1/N) \sum_{j=1}^N \hat{G}(0,v)/(j/N)\hat{\phi}_k(j/N)$. Then we estimate $\Sigma(t,s)$ by $\hat{\Sigma}(t,s) = \sum_{k=1}^K \hat{\lambda}_k \hat{\phi}^{(v)}_k(t)\hat{\phi}^{(v)}_k(s)$.

The following theorem shows that $\hat{\Sigma}(\cdot,\cdot)$ and $\Sigma(\cdot,\cdot)$ are asymptotically equivalent.

**Theorem 4.** Under Assumptions (A1)–(A6), one has

$$
\sup_{(t,s)\in[0,1]^2} \left| \hat{\Sigma}(t,s) - \Sigma(t,s) \right| = o_p(1).
$$

The proof of Theorem 4 is given in Appendix A.4.

In practice, we choose the first $L$ positive eigenvalues $\hat{\lambda}_1 \geq \cdots \geq \hat{\lambda}_L > 0$ by eigenvalue decomposition of $\hat{G}(t,s)$. Then we apply a standard criterion in Müller (2009), to choose the number of eigenfunctions, i.e. $\kappa = \arg \min_{1 \leq L \leq L_0} \left\{ \sum_{k=1}^L \hat{\lambda}_k / \sum_{k=1}^L \hat{\lambda}_k > 0.95 \right\}$. Müller (2009) suggests the “pseudo-AIC” and this simple method of counting the percentage of variation explained can be used to choose the number of principal components. The simple method performed well in our simulations and is used for our numerical studies.

To construct the confidence bands, we use cubic splines to estimate the mean and covariance functions and their first order derivatives. Generalized cross-validation is used to choose the number of knots $N_k$ (from 2 to 20), to smooth out the mean function. According to Assumption (A3), the number of knots for smoothing the covariance function is taken to be $N_G = [n^{1/2p}\log(n)]$, where $[a]$ denotes the integer part of $a$.

Finally, in order to estimate $q_{1-\alpha}$, we generate i.i.d. standard normal variables $Z_{k,b}$, $1 \leq k \leq \kappa$, $b = 1, \ldots, 5000$. Let $\hat{\delta}_b(t) = \hat{\Sigma}(t,t)^{-1/2} \sum_{k=1}^\kappa \sqrt{\hat{\lambda}_k} Z_{k,b} \hat{\phi}^{(v)}_k(t)$, $t \in [0,1]$. $q_{1-\alpha}$ can be estimated by $100(1-\alpha)$-th percentile of $\{\sup_{t \in [0,1]} |\hat{\delta}_b(t)|\}_{b=1}^{5000}$.

Therefore, in application we recommend the following band:

$$
\hat{\mu}^{(v)}(t) \pm n^{-1/2} \hat{\Sigma}(t,t)^{1/2} \hat{\delta}_{1-\alpha}, \quad t \in [0,1].
$$

(12)

**4. Numerical studies**

**4.1. Simulated examples**

To illustrate the finite-sample performance of the confidence band in (12), we generate data from the following:

$$
Y_{ij} = \mu(j/N) + \sum_{k=1}^\kappa \bar{\xi}_k \hat{\phi}_k(j/N) + \epsilon_{ij}, \quad \epsilon_{ij} \sim N(0,0.1^2)
$$

for $1 \leq i \leq n$, $1 \leq j \leq N$. We consider two scnearios.

Model I: $\mu(t) = 5t + 4 \sin(2\pi(t-0.5))$, $\phi_1(t) = -\sqrt{2} \cos(2\pi(t-0.5))$, $\phi_2(t) = \sqrt{2} \sin(4\pi(t-0.5))$, $\bar{\xi}_k \sim N(0,\lambda_k)$, $\lambda_1 = 2$, $\lambda_2 = 1$, $\kappa = 2$;

Model II: $\mu(t) = 4t + (1/2\pi0.1) \exp(-(t-0.5)^2/2(0.1)^2)$, $\phi_1(t) = \sqrt{2} \sin(\pi kt)$, $\bar{\xi}_k \sim N(0,\lambda_k)$, $\lambda_k = 2^{-(k-1)}$, $k = 1, 2, \ldots, \kappa = 8$.

The second case has similar design as in Simulation C of Liu and Müller (2009). We use the proposed method in (12) and its “oracle” version with true $\Sigma(t,t)$ to construct the confidence bands for $\mu^{(v)}(\cdot)$, respectively, in both studies. We consider

two confidence levels: $1 - \alpha = 0.95, 0.99$. The number of trajectories $n$ is taken to be 30, 50, 100, 200, and for each $n$, we try different numbers of observations on the trajectory. Each simulation consists of 1000 Monte Carlo samples.

We evaluate the coverage of the bands over 200 equally spaced points on $[0,1]$ and test whether the true functions are covered by the confidence bands at these points. Tables 1 and 2 show the empirical coverage probabilities out of 1000 replications for Models I and II, respectively. From Tables 1 and 2, we observe that coverage probabilities for both estimated bands and “oracle” bands approach the nominal levels, which show positive confirmation of Theorem 2. In most of the scenarios the “oracle” confidence bands outperform the estimated bands, and the “oracle” bands arrive at about the

**Fig. 1.** Plots of the cubic spline estimators (dotted-dashed line) and 99% confidence bands (upper and lower dashed lines) of $\mu^{(1)}(t)$ (solid line) in Model I.
nominal coverage for large $n$ and $N$. The convergence rates of estimated bands are slower than those “oracle” bands, but the convergence trend to nominal level is clearly.

Figs. 1 and 2 show the estimated functions and their 99% confidence bands for the first order derivative curve $\mu^{(1)}(t)$ for Models I and II, respectively. As expected when $n$ and $N$ increase, the confidence band is narrower and the cubic spline estimator is closer to the true derivative curve. For Model I, the boundary effects in all four panels are almost unnoticeable. For Model II, there seems to be some boundary effects for small $n$ and $N$, which are attenuated as $n$ and $N$ increase.

4.2. Tecator data

Here we apply the proposed method to the Tecator dataset, which can be downloaded from http://lib.stat.cmu.edu/datasets/tecat. This data set contains measurements on $n = 240$ meat samples and for each sample $N = 100$ channel near-infrared spectrum of absorbance measurements were obtained. The Feed Analyzer worked in the wavelength range 850–1050 nm. Fig. 3 shows the estimated mean absorbance measurements $\mu(\cdot)$ in the upper panel and its estimated first order derivative $\mu^{(1)}(\cdot)$ in the lower panel. Their 99% confidence bands (dashed lines) are also included in the figure, both bands have similar band width around 0.1–0.2 even though the bands for $\mu^{(1)}(\cdot)$ looks much narrower in the figure.

As shown in Fig. 3, in the region of 850–950 nm the derivative estimate of mean absorbance is increasing gradually above 0, which corroborates with the convex behavior of the corresponding estimated mean function. For wavelength between 950 and 970 nm, the big bump in the derivative graph is consistent with the changing pattern of the mean estimate before it reaches the turning point at around 970 nm. When wavelength is larger than 970 nm, its estimated derivative turns negative and is relatively flat after 1000 nm, and it is in accordance with the quick dip of the mean absorbance and a linear decreasing trend for wavelength larger than 1000 nm.
The regression function (A1) and the technical assumptions we need are as follows:

The standard deviation function $\sigma(t) \in C^{3,\delta}[0,1]$ for some $\delta \in (0,1]$;

(A3) The number of observations for each trajectory $N \gg n^6$ for some $\theta > (1+2\nu)/2(\nu-v)$; the number of interior knots satisfies $n^{1/2(p-v)} \ll N \ll (N/\log(n))^{(1+2\nu)/(1+2v)}$, $n^{1/2p} \ll N_C \ll n^{1/(2+2v)}$;
We establish next that denoted by \( \phi_k(t) \) of splines. Assumptions (A4) and (A5) concern that the derivatives of principal components have collectively bounded the requirement of the number of observations within each curve to the sample size, and the order of the number of knots. Assumptions (A4) and (A5) concern that the derivatives of principal components have collectively bounded. When \( t = 0 \), Assumption (A5) is the same as (A4) in Cao et al. (forthcoming). Assumption (A6) is necessary when using strong approximation result in Lemma A4.

If \( \kappa \) is finite and all \( \phi_k^{(\nu)}(t) \in C_{p2}^0[0,1] \), then Assumption (A5) on \( \phi_k^{(\nu)} \)'s holds trivially. For \( \kappa = \infty \), Assumption (A5) is fulfilled as long as \( \lambda_k \) decreases to zero sufficiently fast. For example, considering the following canonical orthonormal Fourier basis of \( L_2^2([0,1]) \):

\[
\phi_1(t) \equiv 1, \phi_{2k+1}(t) = \sqrt{2} \cos(k\pi t), \]

\[
\phi_{2k}(t) = \sqrt{2} \sin(k\pi t), \quad k = 1, 2, \ldots, t \in [0,1],
\]

we can take \( \lambda_1 = 1 \) and \( \lambda_k = (k/2)^{-2\nu} \rho^{1/2^k} \) for any \( \rho > 0 \), then \( \sum_{k=1}^\infty \sqrt{\lambda_k} \phi_k^{(\nu)}(t) = 1 \) and \( \rho \equiv \sqrt{2} + \sqrt{2} = 1 + \sqrt{2} \rho (1 - \rho)^{-2} \). While for any \( \rho > 0 \) and \( (k_N)^{\infty}_{n=1} \) with \( k_N \to \infty \), one has

\[
N_\rho^{-2} \sum_{k=1}^{\infty} \sqrt{\lambda_k} \phi_k^{(\nu)}(t) = N_\rho^{-2} \sum_{k=1}^{(k_N-1)/2} \rho^2 \sqrt{2\pi N_\rho^{-1}} \rho \sum_{k=1}^{(k_N-1)/2} \rho^k = 2 \sqrt{2} \pi N_\rho^{-1} \rho \sum_{k=1}^{(k_N-1)/2} \rho^k = O(N_\rho^{-1}) = o(1).
\]

In the following, define the theoretical and empirical inner product matrices of \( \{B_j(t)\}_{j=1}^{N_\rho} \) as

\[
V_p = \langle B_j(t), B_j(t) \rangle_{j=1}^{N_\rho} = \rho \sum_{q=0}^{\nu} \langle B_j(t), B_j(t) \rangle_{j=1}^{N_\rho} = O(N_\rho).
\]

We establish next that \( V_p \) has an inverse with bounded \( L_\infty \) norm.

**Lemma A1** (Cao et al., forthcoming). Under Assumption (A3), for \( V_p \) and \( \tilde{V}_p \) defined in (A1), \( \|V_p - \tilde{V}_p\| = O(n^{-1}) \) and \( \|V_p\| = O(n) \).

### A.1. Proof of Proposition 1

Following Wang and Yang (2009b), we introduce the \( p \)-th order quasi-interpolant of \( \mu \) corresponding to the knots \( \varpi \), denoted by \( Q_p(\mu) \); see DeVore and Lorentz (1993, Eq. (4.12) on p. 146) for details. According to DeVore and Lorentz (1993, Theorem 7.7.4), the following lemma holds.

**Lemma A2.** There exists a constant \( C > 0 \), such that for \( 0 \leq \nu \leq p-2 \) and \( \mu \in C^{0,1}[0,1] \),

\[
\|\mu - Q_p(\mu)\|_p \leq C\|\mu\|_p\|h_p^{p-\nu}.
\]

**Lemma A3.** Under Assumptions (A2), (A3) and (A6), one has

\[
\frac{1}{N} \sum_{j=1}^{N} B_j(t) / \sigma(j/N) \bar{e}_j = O_p \left( \sqrt{\log(n)} / \sqrt{N} \right).
\]

**Proof.** We first truncate the random error \( i_j \) by \( U_n = (nN)^{\gamma} (2/9 < \gamma < 1/3) \) and write \( i_j = i_{j,1} + i_{j,2} + i_{j,3} \), where \( i_{j,1} = E[i_j \mid i_j > U_n] \), \( i_{j,2} = E[i_j \mid i_j \leq U_n] - a_j \) and \( a_j = E[i_j \mid i_j \leq U_n] \). It is easy to see that \( |a_j| = |i_j - E[i_j \mid i_j > U_n]| \leq E(i_j - U_n) \). It is straightforward from the boundedness of spline basis that

\[
\left| \frac{1}{nN} \sum_{j=1}^{nN} B_j(t) / \sigma(j/N) \sum_{i=1}^{nN} \bar{e}_j \right| = O\left( n^{-1/2} \right).
\]

Next we show that the tail part vanishes almost surely. Note that

\[
\sum_{n=1}^{\infty} P(i_j > U_n) \leq \sum_{n=1}^{\infty} E[i_j^4 + \delta_2] / U_n^{4 + \delta_2} \leq M_1 \sum_{n=1}^{nN} U_n^{4 + \delta_2} \leq \infty.
\]
By the Borel–Cantelli lemma, \( P(\omega) \geq N(\omega), |e_{ij}(\omega)| \leq u_{ij} \) for \( n > N(\omega) \) = 1. Let \( v_{\omega} = \max(|e_{ij}|, 1 \leq i, j \leq N(\omega)) \) and there exists \( N(\omega) > N(\omega), u_{nj}(\omega) > v_{\omega} \). Since \( u_{nj}(\omega) = (n^{\delta}) \) is an increasing function, \( u_{nj}(\omega) > v_{\omega} \).  

Therefore \( P(\omega) \geq N(\omega), |e_{ij}(\omega)| \leq u_{nj}(\omega), 1 \leq i, j \leq n, 1 \leq j \leq N \), for \( \min(n, N) > N(\omega) \) = 1, which implies \( P(\omega) \geq N(\omega), |e_{ij1}| = 0, 1 \leq i, n, 1 \leq j \leq N \) for \( \min(n, N) > N(\omega) \) = 1. Thus

\[
\frac{1}{nN} \sum_{j=1}^{n} B_{ij}(j/N) \sqrt{\sigma} \sum_{i=1}^{n} e_{ij} = 0_{d_.N}(n)^{-k}. \text{ for any } k > 0.
\]

Next denote \( D_{j} = (n^{\delta})^{-1} B_{ij}(j/N) \sqrt{\sigma} \sum_{i=1}^{n} e_{ij} \). Since \( \text{Var}(x_{ij}) = 1 - E[x_{ij}^{2}] > u_{nj}(\omega) - a_{ij}^{2} = 1 + O[n^{\delta}] \), one has \( \sqrt{N} = \text{Var}(\sqrt{N}^{-1} D_{j}) = c(nN^{\delta})^{-1} \) for a constant \( c > 0 \). Now Minkowski’s inequality implies that \( E[x_{ij}^{2}] = 2 - 2^{k-1} E[x_{ij}^{2}] \leq 2^{k-2} n^{\delta} x_{ij}^{2} k^{\delta}, k \geq 2 \). Thus \( E[D_{j}]^{k} \leq (2n^{-1} - 1) u_{nj}^{k-2} \leq E[D_{j}]^{2} \) with the Cramer constant \( c = 2u_{nj}/nN \). For any \( \delta, \delta_{n} = \delta \sqrt{\log(n)} / nN^{\delta} \). By the Bernstein inequality, for any large enough \( \delta > 0 \),

\[
P \left( \sum_{j=1}^{n} D_{j} \geq 0 \right) \leq 2 \exp \left( \frac{-\delta_{n}^{2}}{4v_{n}^{2} + 2c^{2} \delta_{n}} \right) \leq 2 \exp \left( \frac{-\delta_{n}^{2}}{4c nNN^{\delta} + 4\delta_{n} nN^{\delta}} \right) \leq 2n^{-3}.
\]

Hence \( \sum_{j=1}^{n} P (|\sum_{j=1}^{n} B_{ij}(j/N) \sqrt{\sigma} \sum_{i=1}^{n} e_{ij} | \geq \delta_{n}) \leq 2 \sum_{j=1}^{n} n^{-3} < 0 \), for such \( \delta > 0 \). Thus Borel–Cantelli’s lemma implies the desired result.

**Lemma A4** (Csörgö and Révész, 1981, Theorem 2.6.7). Suppose that \( \xi_{ij}, 1 \leq i, n \) are i.i.d. with \( E(\xi_{ij}) = 0, E(\xi_{ij}^{2}) = 1 \) and \( H(x) > 0 \) (\( x \geq 0 \)) is an increasing continuous function such that \( x^{-1} H(x) \) is increasing for some \( \gamma > 0 \) and \( x^{-1} \log H(x) \) is decreasing with \( EH(\xi_{ij}) < \infty \). Then there exist constants \( C_{1}, C_{2}, a > 0 \) which depend only on the distribution of \( \xi_{ij} \) and a sequence of Brownian motions \( \text{W}(n^{\delta}) \) \( \text{W}(n_{j}) \), such that for any \( (x_{n})_{n=1}^{\infty}, \) such that \( \text{H}(n^{\delta}) < \infty \), \( \text{W}(n_{j}) \), and \( \text{S}_{n} = \sum_{i=1}^{n} \xi_{ij} \), then \( P(\max_{1 \leq s \leq n} |\text{W}(n_{s}) - \text{W}(n_{s-1})| > 1) \leq C_{2} n^{-H(x)} \).

**Proof of Proposition 1.** We first show (6). According to Theorem A.1 of Huang (2003), there exists an absolute constant \( C > 0 \), such that

\[
\|\hat{\mu} - \mu\|_{\infty} \leq C \inf_{\delta \in [0, 1]} \|g - \mu\|_{\infty} \leq C\|\mu(\mu)\|_{\infty} h_{\mu}^{\delta}, \tag{A.2}
\]

Applying Lemma A2, for \( 0 \leq v \leq p–2 \),

\[
\|Q_{\hat{\mu}}(\mu) - \mu\|_{\infty} \leq C\|\mu(\mu)\|_{\infty} h_{\mu}^{p–v}. \tag{A.3}
\]

As a consequence of (A.2) and (A.3) if \( v = 0 \), one has \( \|Q_{\hat{\mu}}(\mu) - \hat{\mu}\|_{\infty} = C\|\mu(\mu)\|_{\infty} h_{\mu}^{p–v} \), which, according to the differentiation of B-spline given in de Boor (2001), entails that

\[
\|Q_{\hat{\mu}}(\mu) - \hat{\mu}\|_{\infty} \leq C\|\mu(\mu)\|_{\infty} h_{\mu}^{p–v} \tag{A.4}
\]

for \( 0 \leq v \leq p–2 \). Combining (A.3) and (A.4) proves (6) for \( v = 1, \ldots, p–2 \).

Next we prove (7). Similar to the definition of \( \hat{\mu}^{(v)}(t) \) and \( \hat{\xi}^{(v)}(t) \), in the following we denote \( \hat{\varphi}^{(v)}(t) = \hat{\varphi}^{(v)}(t) \), for any \( k \geq 1 \). Using the similar arguments as in the proof of (6), we can show that, for any \( k \geq 1 \),

\[
\|\varphi^{(v)}(t) - \varphi^{(v)}(t)\|_{\infty} \leq C\|\mu(\mu)\|_{\infty} h_{\mu}^{p–v} \tag{A.5}
\]

Also, according to triangle inequality one has that \( \|\varphi^{(v)}(t)\|_{\infty} \leq C\|\varphi^{(v)}(t)\|_{\infty} = O(1) \).

According to Assumption (A6), \( E[\xi_{lk}^{4}] < \infty, \xi_{lk} > 0 \), so there exists some \( \beta \in (0, 1/2) \), such that \( 4 + \beta > 2/\beta \). Let \( H(x) = x^{4} + \beta, \) then \( H(\alpha x) = a^{-4} \beta n^{1-(4+\beta)} = O(n^{-\gamma}) \) for some \( \gamma > 1 \). Applying Lemma A4 and Borel–Cantelli Lemma, one finds i.i.d. variables \( Z_{ik}, k \sim N(0, 1) \) such that

\[
\max_{k \geq 1} |Z_{ik}| = O_{\infty}(n^{\beta–1}). \tag{A.6}
\]

where \( Z_{ik} = n^{-1} \sum_{i=1}^{n} Z_{ik}, k \geq 1 \).

If \( k \) is finite, according to (A.6) note that \( |Z_{ik}| \leq |Z_{ik}| \sqrt{\sum_{k}} + |Z_{ik} - Z_{ik}| \sqrt{\sum_{k}}, 1 \leq k \leq k, \) so \( \max_{1 \leq k} |Z_{ik}| = O_{\infty}(n^{-1/2} + n^{\beta–1}) \). Then the definition of \( \|\hat{\varphi}^{(v)}(t)\|_{\infty} \) (4) and (A.5) entail that

\[
\|\varphi^{(v)}(t) - \varphi^{(v)}(t)\|_{\infty} \leq \max_{1 \leq k \leq K} \|Z_{ik}\|_{\infty} \max_{1 \leq k \leq K} \|\varphi^{(v)}(t) - \varphi^{(v)}(t)\|_{\infty} \leq O_{\infty}(n^{-1/2}).
\]

Thus (8) holds according to Assumption (A3).
If $\kappa = \infty$, using similar arguments in Cao et al. (forthcoming), by (A6) one can show that $|\zeta_{k}^2|^{1/2} = \left|Z_{k}^2 \cdot \zeta_{k}^{1/2} - Z_{k} \cdot \zeta_{k}^{1/2}\right|$, for any $k \geq 1$, so $|\zeta_{k}^2|^{1/2} = O_p(n^{-1/2} + \delta^{-1})$. Also following Assumption (A5) one has

$$E \sup_{\theta \in [0,1]} |\tau(\theta) - \mu(\theta) - \tau(\theta)| \leq \sum_{k=1}^{K} E \left[ |\zeta_{k}^2|^{1/2} \right] \sup_{\theta \in [0,1]} |\mu(\theta) - \mu(\theta)|$$

Thus (8) holds according to Assumption (A3).

A.2. Proof of Theorem 2

We denote $\tilde{\tau}(t) = \sqrt{\tau(t)} \zeta(t)$, $\tilde{\zeta}(t) = \sqrt{\zeta(t)} \zeta(t)$, $k = 1, \ldots, \kappa$ and define

$$\tilde{\tau}(t) = n^{1/2} \left[ \sum_{k=1}^{K} \lambda_k(\phi_k(t))^2 \right]^{-1/2} \sum_{k=1}^{K} \zeta_k(t) = n^{1/2} \Sigma(t, t)^{-1/2} \sum_{k=1}^{K} \zeta_k(t).$$

It is clear that, for any $t \in [0,1]$, $\tilde{\tau}(t)$ is Gaussian with mean 0 and variance 1, and the covariance $E \left[ \tilde{\tau}(t) \tilde{\tau}(s) \right] = \Sigma(t, t)^{-1/2} \Sigma(s, s)^{-1/2} \Sigma(t, s)$, for any $t, s \in [0,1]$. That is, the distribution of $\tilde{\tau}(t), t \in [0,1]$ and the distribution of $\tilde{\zeta}(t), t \in [0,1]$ in Section 3.1 are identical. Similar to the proof of (7), Note that

$$E \sup_{\theta \in [0,1]} |\tilde{\tau}(\theta) - n^{1/2} \Sigma(t, t)^{-1/2} \tilde{\tau}(\theta)|$$

$$= n^{1/2} E \sup_{\theta \in [0,1]} \Sigma(t, t)^{-1/2} \sum_{k=1}^{K} \tilde{\tau}(t) - \tilde{\tau}(\theta)$$

$$\leq n^{1/2} E \sup_{\theta \in [0,1]} \Sigma(t, t)^{-1/2} \sum_{k=1}^{K} \left( |\zeta_k| \sqrt{\phi_k(t)} |\phi_k(\theta)| + |\zeta_k| |\phi_k(t) - \phi_k(\theta)| \right).$$

If $\kappa$ is finite, then $\sup_{\theta \in [0,1]} |\tilde{\tau}(\theta) - n^{1/2} \Sigma(t, t)^{-1/2} \tilde{\tau}(\theta)| = O(n^{-1/2} + \delta^{-1}) = o(1)$. If $\kappa = \infty$, by Assumption (A5) one has

$$n^{1/2} E \sup_{\theta \in [0,1]} \Sigma(t, t)^{-1/2} \sum_{k=1}^{K} \left( |\zeta_k| \sqrt{\phi_k(t)} |\phi_k(\theta)| + |\zeta_k| |\phi_k(t) - \phi_k(\theta)| \right)$$

$$\leq n^{1/2} \sup_{\theta \in [0,1]} \Sigma(t, t)^{-1/2} \left\{ n^{-1/2} \sum_{k=1}^{K} \sqrt{\phi_k(t)} |\phi_k(\theta)| + n^{-1/2} \sum_{k=1}^{K} \sqrt{\phi_k(t)} |\phi_k(t) - \phi_k(\theta)| \right\}$$

$$= o(1).$$

Theorem 2 follows directly.

A.3. Proof of Theorem 3

Following Cao et al. (2011), we define the tensor product spline space as

$$\mathcal{N}^{(p-2)}[0,1] \equiv \mathcal{N}^{(p-2)} \otimes \mathcal{N}^{(p-2)} = \left\{ \sum_{i=1}^{N} b_i B_{i,p}(t) B_{i,p}(s), t, s \in [0,1] \right\}.$$ 

Let $R_{ij} \equiv Y_{ij} - \mu(j/N)$, $1 \leq i \leq n$, $1 \leq j \leq N$ and $R_{ij} = n^{-1} \sum_{i=1}^{N} R_{ij}$, $1 \leq j \leq N$. Note that the spline estimator in (9) is

$$\hat{G} = \arg \min_{G \in \mathcal{N}^{(p-2)}} \left\{ \sum_{j \neq j} \left( R_{ij} - g(j/N) / N \right)^2 \right\},$$

so we define the “infeasible estimator” of the covariance function

$$\hat{G} = \arg \min_{G \in \mathcal{N}^{(p-2)}} \left\{ \sum_{j \neq j} \left( R_{ij} - g(j/N) / N \right)^2 \right\}.$$
Denote \( \mathbf{X} = \mathbf{B} \otimes \mathbf{B}, \mathbf{B}_p(t,s) = \mathbf{B}_p(t) \otimes \mathbf{B}_p(s) \) and \( \mathbf{B}_p^{(0,v)}(t,s) = \mathbf{B}_p(t) \otimes \mathbf{B}_p^{(0)}(s) \). Let vector \( \mathbf{R} = [\mathbf{R}_{ij}]_{1 \leq i,j \leq N} \), then we have
\[
\dot{G}^{(0,v)}(t,s) = \nabla^2_{t,s} \hat{G}(t,s) = \mathbf{B}_p^{(0,v)}(t,s) \mathbf{X}^T \mathbf{X}^{-1} \mathbf{X}^T \mathbf{R}.
\]
(A.8)

In the following we write \( \phi_{kk}(t,s) = \phi_k(t)\phi_k(s), \phi_{kk}^{(0,v)}(t,s) = \phi_k(t)\phi_k^{(0)}(s) \). Let \( \phi_{kk} = \phi_k \otimes \phi_k^{(0)} \), where \( \phi_k \) is a \( N \)-dimensional vector defined in Section 2.3. \( \hat{\phi}_{kk}(t,s) = \mathbf{B}_p(t,s) \mathbf{X}^T \mathbf{X}^{-1} \mathbf{X}^T \phi_{kk} \). Further we denote \( \phi_{kk}^{(0,v)}(t,s) = \mathbf{B}_p^{(0,v)}(t,s) \mathbf{X}^T \mathbf{X}^{-1} \mathbf{X}^T \phi_{kk} \).

**Lemma A5.** Under Assumptions (A5), for any \( 1 \leq v \leq p-2 \), and \( \kappa = \infty \), one has
\[
\sum_{k,k' \geq 1} \sqrt{\lambda_k \lambda_{k'}} \| \phi_{kk}^{(0,v)} - \tilde{\phi}_{kk}^{(0,v)} \|_\infty = o(1).
\]
**Proof.** When \( \kappa = \infty \), one has \( \lambda_k > 0 \) for any \( k \geq 1 \). Note that
\[
\sum_{k,k' \geq 1} \sqrt{\lambda_k \lambda_{k'}} \| \phi_{kk}^{(0,v)} \|_\infty \leq \sum_{k \geq 1} \sqrt{\lambda_k} \| \phi_k \|_\infty \sum_{k' \geq 1} \sqrt{\lambda_{k'}} \| \phi_{k'}^{(0,v)} \|_\infty = o(1).
\]
Also similarly,
\[
\sum_{k,k' \geq 1} \sqrt{\lambda_k \lambda_{k'}} \| \phi_{kk}^{(0,v)} \|_\infty \leq \sum_{k \geq 1} \sqrt{\lambda_k} \| \phi_k \|_\infty \sum_{k' \geq 1} \sqrt{\lambda_{k'}} \| \phi_{k'}^{(0)} \|_\infty \leq C \sum_{k \geq 1} \sqrt{\lambda_k} \| \phi_k \|_\infty \sum_{k' \geq 1} \sqrt{\lambda_{k'}} \| \phi_{k'}^{(0)} \|_\infty = o(1).
\]

**Lemma A6.** Under Assumption (A5), for any \( 0 \leq v \leq p-2 \) and \( k,k' \geq 1 \), one has \( \| \phi_{kk}^{(0,v)} - \tilde{\phi}_{kk}^{(0,v)} \|_\infty = o(h_G^{p,v}) \).
**Proof.** According to Theorem 12.8 of Schumaker (2007), there exists an absolute constant \( C > 0 \), such that
\[
\| \hat{\phi}_{kk} - \phi_{kk} \|_\infty \leq C \| \phi_{kk}^{(p,v)} \|_\infty h_G^{p,v},
\]

which proves (6) for the case \( v = 0 \). Let (Q(f)) the \( p \)-th order quasi-interpolant of a function \( f \); see the definition in (12.29) of Schumaker (2007), for \( 0 \leq v \leq p-2 \),
\[
\| (Q(f) - \hat{\phi}_{kk})^{(0,v)} \|_\infty \leq C \| \phi_{kk}^{(p,v)} \|_\infty h_G^{p,v}.
\]

For the case \( v = 0 \), one has
\[
\| (Q(f) - \tilde{\phi}_{kk})^{(0,v)} \|_\infty = \| (Q(f) - Q(\tilde{\phi}_{kk})) \|_\infty \leq C \| \phi_{kk}^{(p,v)} \|_\infty \leq C \| \phi_{kk}^{(p,v)} \|_\infty h_G^{p,v}
\]

which, according to the differentiation of B-spline given in de Boor (2001), entails that \( \| (Q(f) - \tilde{\phi}_{kk})^{(0,v)} \|_\infty \leq C \| \phi_{kk}^{(p,v)} \|_\infty h_G^{p,v} \), for \( 0 \leq v \leq p-2 \).

**Lemma A7.** Under Assumptions (A1)–(A6), for any \( 1 \leq v \leq p-2 \)
\[
\| \dot{G}^{(0,v)} - G^{(0,v)} \|_\infty = O_p(n^{-1/2} + h_G^{p,v} + O_p(N^{-1} n^{-1/2} h_G^{-1}) \log^{1/2} n), \tag{A.9}
\]
\[
\| \ddot{G}^{(0,v)} - G^{(0,v)} \|_\infty = O_p(n^{-1} h_G^{-3/2} + n^{-1} h_G^{-1}) h_p, \tag{A.10}
\]

where \( \dot{G}^{(0,v)} \) and \( \ddot{G}^{(0,v)} \) are given in (10) and (A.8).

**Proof.** Let \( \bar{z}_{kk} = n^{-1} \sum_{i=1}^{n} z_{kk}^{(i)} \) and \( \bar{w}_{jj} = n^{-1} \sum_{i=1}^{n} w_{jj}^{(i)} \). To show (A.9), we decompose \( \mathbf{R}_{ij} \) in (A.7) into
\[
\mathbf{R}_{ij} = \sum_{k' \neq k} \bar{z}_{kk'} \tilde{\phi}_{kk'} \left( \frac{j}{N} \right) \left( \frac{i}{N} \right), \quad \mathbf{R}_{ij} = \sum_{k=1}^{K} \bar{z}_{kk} \phi_{kk} \left( \frac{j}{N} \right) \left( \frac{i}{N} \right), \quad \mathbf{R}_{ij} = \sigma \left( \frac{j}{N} \right) \sigma \left( \frac{i}{N} \right) \tau_{ij},
\]
\[
\mathbf{R}_{ij} = n^{-1} \sum_{i=1}^{n} \left\{ \sum_{k=1}^{K} \bar{z}_{kk} \phi_{kk} \left( \frac{j}{N} \right) \sigma \left( \frac{j}{N} \right) \sigma \left( \frac{i}{N} \right) \right\}.
\]

Denote \( \mathbf{R}_i \) as \( [\mathbf{R}_{ij}]_{1 \leq i,j \leq N} \). \( \mathbf{R}^{(0,v)}(t,s) = \mathbf{B}_p^{(0,v)}(t,s) \mathbf{X}^T \mathbf{X}^{-1} \mathbf{X}^T \mathbf{R}_i, i = 1,2,3,4 \). Then \( \dot{G}^{(0,v)}(t,s) = \mathbf{R}_1^{(0,v)}(t,s) + \mathbf{R}_2^{(0,v)}(t,s) + \mathbf{R}_3^{(0,v)}(t,s) + \mathbf{R}_4^{(0,v)}(t,s) \). Next we define
\[
\mathbf{R}_1^{(0,v)}(t,s) = \sum_{k=1}^{K} \bar{z}_{kk} \phi_{kk}^{(0,v)}(t,s),
\]
\[
\mathbf{R}_2^{(0,v)}(t,s) = G^{(0,v)}(t,s) + \sum_{k=1}^{K} \{ \phi_{kk}^{(0,v)}(t,s) (\bar{z}_{kk} - \bar{w}_{kk}) \}.
\]
Note that \( \check{R}_1^{(v)}(t,s) = \sum_{k \neq k'} \check{z}_{kk'} \Phi_{kk'}^{(v)}(t,s) \), then Lemma A5 and Assumption (A5) imply that if \( \kappa \) is \( \infty \), \( \lambda_k \lambda_{k'} > 0 \) and one has
\[
\sup_{(t,s) \in [0,1]^2} E[|\check{R}_1^{(v)}(t,s) - \check{R}_1^{(v)}(t,s)|] \leq \sum_{k = 1}^{\infty} E[|\check{z}_{kk'} \lambda_k \lambda_{k'}^{-1/2} \sqrt{\lambda_k \lambda_{k'}^2 \Phi_{kk'}^{(v)} - \Phi_{kk'}^{(v)}}|_{\infty}] = o(1).
\]
Similarly, one has
\[
\sup_{(t,s) \in [0,1]^2} E[|\check{R}_2^{(v)}(t,s) - \check{R}_2^{(v)}(t,s)|] \leq \sum_{k = 1}^{\infty} E[|\check{z}_{kk'} \lambda_k \lambda_{k'}^{-1} - 1| \lambda_k \lambda_{k'} \Phi_{kk'}^{(v)} - \Phi_{kk'}^{(v)}|_{\infty}] = o(1).
\]
If \( \kappa \) is finite, then Lemma A6 and Assumption (A3) imply that
\[
\|\check{R}_1^{(v)} - \check{R}_1^{(v)}\|_{\infty} \leq \kappa \max_{1 \leq k \leq \kappa} |\check{z}_{kk'}| \|\Phi_{kk'}^{(v)} - \Phi_{kk'}^{(v)}\|_{\infty} = O_p(h_C n^{-1/2}).
\]
Similarly,
\[
\|\check{R}_2^{(v)} - \check{R}_2^{(v)}\|_{\infty} \leq \kappa \max_{1 \leq k \leq \kappa} |\check{z}_{kk'} - \lambda_k| \|\Phi_{kk'}^{(v)} - \Phi_{kk'}^{(v)}\|_{\infty} = O_p(h_C n^{-1/2}).
\]
Hence, \( \|\check{R}_1^{(v)} - \check{R}_2^{(v)}\|_{\infty} \leq \|\check{R}_1^{(v)} - \check{R}_1^{(v)}\|_{\infty} + \|\check{R}_1^{(v)} - \check{R}_1^{(v)}\|_{\infty} = o(1) \). By Proposition 3.1 in Cao et al. (2011), one has
\[
\|N^{-2} X^T R_{31}\|_{\infty} = \|N^{-2} X^T R_{4}\|_{\infty} = O_P(N^{-1} n^{-1/2} h_C \log^{1/2}(n)).
\]
Hence, \( \|\check{R}_3^{(v)}\|_{\infty} = \|\check{R}_4^{(v)}\|_{\infty} = O_P(N^{-1} n^{-1/2} h_C \log^{1/2}(n)) \).

The proof of (A.10) is similar to Proposition 2.1 in Cao et al. (2011), thus omitted. \( \square \)

**Proof of Theorem 3.** According to Lemma A7, one has
\[
\|\check{G}^{(v)} - G^{(v)}\|_{\infty} \leq \|\check{G}^{(v)} - G^{(v)}\|_{\infty} + \|\check{G}^{(v)} - G^{(v)}\|_{\infty} = O_P(1). \quad \square
\]

**A.4. Proof of Theorem 4**

We first show asymptotic consistency of \( \hat{\lambda}_k \) and \( \hat{\Phi}_k(\cdot) \), for \( k \geq 1 \), in the following lemma.

**Lemma A8.** Under Assumptions (A1)–(A6), one has
\[
|\hat{\lambda}_k - \lambda_k| = o_P(1), \quad \|\hat{\Phi}_k - \Phi_k\|_{\infty} = o_P(1), \quad k \geq 1.
\]

**Proof.** We first want to show that for any \( k \geq 1 \), \( \|\Delta \Phi_k\|_{\infty} = o_P(1) \), in which \( \Delta \) is the integral operator with kernel \( \check{G} - G \). Note that \( \Delta \Phi_k(t) = \int (\check{G} - G)(s,t) \Phi_k(s) ds \). By Theorem 3, when \( v = 0 \), \( \|\check{G} - G\|_{\infty} = o_P(1) \). Thus, for any \( k \geq 1 \), \( \|\Delta \Phi_k\|_{\infty} = o_P(1) \).

Hall and Hosseini-Nasab (2006) gives the \( L^2 \) expansion
\[
\hat{\Phi}_k - \Phi_k = \frac{\sum_{k \neq k'} (\lambda_k - \lambda_{k'})^{-1} \langle \Delta \Phi_k, \Phi_k \rangle \Phi_k}{\|\hat{A}\|_2^2},
\]
where \( \|\hat{A}\|_2 = \left( \int \|\check{G} - G(s,t)\|^2 ds dt \right)^{1/2} \). By Bessel’s inequality, one has \( \|\hat{\Phi}_k - \hat{\Phi}_k\|_2 \leq C(\|\Delta \Phi_k\|_2 + \|\hat{A}\|_2) = o_P(1) \). By (4.9) in Hall et al. (2006) and Theorem 3
\[
|\hat{\lambda}_k - \lambda_k| = \int |\check{G} - G(s,t)\Phi_k(s)\Phi_k(t) ds dt + O(\|\Delta \Phi_k\|_2^2) = o_P(1).
\]
Thus \( |\hat{\lambda}_k - \lambda_k| = o_P(1) \) for any \( k \geq 1 \). Next note that
\[
\hat{\lambda}_k \hat{G}(t) - \lambda_k \check{G}(t) = \int \check{G}(s,t)\hat{\Phi}_k(s) ds - \check{G}(s,t)\Phi_k(s) ds = \int \check{G} - G(s,t)(\hat{\Phi}_k(s) - \Phi_k(s)) ds + \int (\check{G} - G(s,t)\hat{\Phi}_k(s) ds + \int \check{G}(s,t)(\hat{\Phi}_k(s) - \Phi_k(s)) ds.
\]
By the Cauchy–Schwarz inequality, uniformly for all \( t \in [0,1] \)
\[
\int \check{G}(s,t)(\hat{\Phi}_k(s) - \Phi_k(s)) ds \leq \left( \int \check{G}^2(s,t) ds \right)^{1/2} \|\hat{\Phi}_k - \Phi_k\|_2 = o_P(1).
\]
Similar arguments and Theorem 3 imply that \( \int (\hat{G} - G)(s,t)(\hat{\phi}_k(s) - \phi_k(s)) \, ds = o_p(1) \) and \( \int (\hat{G} - G)(s,t)\phi_k(s) \, ds = o_p(1) \). All the above together yield \( k\hat{\phi}_k - k\phi_k \to 0 \). By the triangle inequality and
\[
\|k\hat{\phi}_k - k\phi_k\|_{\infty} \leq \|k\hat{\phi}_k - k\phi_k\|_{\infty} + \|k\lambda_k - k\lambda_k\|_{\infty} = o_p(1),
\]
the second result in Lemma A8 follows directly. □

**Proof of Theorem 4.** According to Lemma A8 and Theorem 3, one has
\[
\|\phi_k(s) - \hat{\phi}_k(s)\| = \left| \int_0^1 G_0^{(s)}(t,s)\hat{\phi}_k(t) \, dt - \int_0^1 G_0^{(s)}(t,s)\phi_k(t) \, dt \right| 
\leq \|k\hat{\phi}_k - k\phi_k\|_{\infty} \times \int_0^1 |G_0^{(s)}(t,s)| \, dt + \|k\lambda_k - k\lambda_k\|_{\infty} \int_0^1 G_0^{(s)}(t,s)\phi_k(t) \, dt \, dt.
\]
Hence, \( \sup_{s \in [0,1]} \int_0^1 |(G_0^{(s)} - \hat{G}_0^{(s)})(t,s)\hat{\phi}_k(t) + G(t,s)\phi_k(t) - \hat{\phi}_k(t) \, dt| = o_p(1) \) and \( \|\hat{\phi}_k - \phi_k\|_{\infty} = o_p(1) \). Theorem 4 follows from the definition of \( \Sigma(t,s) \).
